Abstract of EP0030822

A body-adsorbable polymeric material for surgical implantation which is a condensation product of reacting a diamine with lactic or glycolic acid to form a diamidediol which is then reacted with a bischloroformate or a compound selected from the group consisting of dicarboxylic acids, methyl and ethyl esters of dicarboxylic acids, diacidchlorides, and anhydrides of a dicarboxylic acid. The polymeric material has a high degree of softness and flexibility and it is useful as synthetic absorbable surgical sutures.

Synthetic absorbable surgical devices of polyester amides and process for making them

This invention relates to new and useful bioabsorbable polymeric materials derived from reacting diamidediols with a dicarboxylic acid or a bischloroformate and to the methods for the preparation of such polymeric materials.

It has become common practice in human and animal surgery to utilize various augmentation devices to restore living tissues or repair various organs. These surgical augmentation devices are placed in position either temporarily or permanently. One such augmentation device is a surgical suture.

Surgical sutures were originally fabricated from naturally occurring substances. Such naturally occurring materials include silk and catgut or collagen. Although these naturally occurring materials are still in widespread use, modern synthetic fibers made of nylons, polyesters, polyolefins and the like are steadily displacing these natural materials for a variety of reasons. For example, synthetic fibers generally cause far less adverse tissue reactions and are less likely to potentiate infection than either silk or catgut.

If placed for temporary purposes, the suture should be made so that it is absorbed by the body after serving its function in the augmentation or wound repair process. "Absorbed" is used herein to mean that a substantial portion of the polymer is metabolized by the body and ultimately eliminated therefrom.

Several absorbable sutures are presently known in the art. For example, see U.S. Patents 3,636,956 and 3,839,297. The sutures disclosed in the aforementioned patents consist of an extrusion of a polylactide polymer which includes a copolymer of L(-)lactide with up to 35 mole percent of glycolide. While multifilament sutures manufactured from polymers of lactide and glycolide fulfil the requirements of a suture to a large degree, monofilament sutures of these materials are considerably less flexible than catgut and these synthetic sutures are accordingly generally limited to a multifilament, braided construction. Braided sutures have the disadvantages of causing trauma upon being pulled through tissue due to a sawing action, also known as tissue drag. Sutures of glycolide polymers are also not suitable for sterilization by radiation without suffering severe degradation of physical properties.

Another serious disadvantage of the polyglycolide sutures is the fact that strength loss *in vivo* proceeds at a rapid rate. Such fibers are known to possess virtually no strength at three to four weeks. While this is not a problem in some applications, the polyglycolide sutures are contraindicated where extended approximation is advisable.

Ullmanns Encyklopädie der technischen Chemie, 4th Edition, Volume 18, 1979, Verlag Chemie, Weinheim, page 173, relates to properties of some polyester and polyamide polymers having biomedical use. FR—A—2 140 368 (Goodman reference), the U.S. equivalent of which is Re. 30,170, relates to hydrolyzable polymers of amino acid and hydroxy acids. All polymers disclosed are derived from α -amino acids. Journal of Applied Polymer Science, Vol. 90, no. 4, 1976, John Wiley, New York, U.S.A., page 975 (Katayama reference) relates to alternating polyester amides having a 5-carbon bridging group between the hydroxy moiety and the amide moiety of the unit structure. The reference teaches reacting a diamine with a caprolactone to produce a diamidediol.

The present invention provides synthetic absorbable sutures having a high degree of softness and flexibility while at the same time allowing the sutures to be used in monofilament form. The sutures can also be sterilized with gamma radiation (e.g., radiation from cobalt 60) without serious loss of suture strength. It is accordingly an object of the present invention to provide synthetic absorbable sutures having unique and desirable properties not available with the sutures of the prior art.

The synthetic absorbable sutures of the present invention are prepared from a polymeric material having plurality of units of the general formula:

wherein

R¹ is hydrogen or methyl;

R³ and R⁵ may be identical or different and are selected from the group consisting of the following which may be linear or branched alkylene, alkylene having 1 to 2 nonadjacent catenary oxygen or sulfur atoms, and alkenylene; cycloalkylene and arylene; and having 4 to 25 carbon atoms in the cyclic compounds and from 2 to 25 carbon atoms in the non-cyclic;

R² and R⁴ are hydrogen or alkyl having 1 to 4 carbon atoms or R² and R⁴ together are linear or branched alkylene having one to four carbons forming with N—R³—N a heterocyclic group having 5 or 6 ring atoms; and

a and b are independently zero or one.

In a preferred embodiment of the polymeric surgical material of the invention, a and b are zero and R⁵ is ethylene; it is additionally preferred that R¹, R² and R⁴ are hydrogen and R³ is a mixture of 1,12-didecamethylene and 1,12-(4,9-dioxadodecamethylene). It is also preferred that the said material has 10 to 100 segments of repeating units of said polymer.

6 The polymeric materials of the present invention may be prepared by utilizing a process which comprises the steps of:

reacting a diamine with lactic or glycolic acid to form a diamidediol;

and reacting said diamidediol with a bischloroformate or a diacid compound which is selected from dicarboxylic acids, methyl and ethyl esters of dicarboxylic acids, diacidchlorides, and anhydrides of 10 dicarboxylic acids.

The polymeric material can then be processed to the desired configuration.

The body-absorbable surgical materials of the present invention are comprised of a polymer of the general formula:

20 in which

R¹, R², R³, R⁴, R⁵, a and b are as defined above; and

n has an average value from about 10 to about 100.

In order to obtain the regular sequence shown, it is desirable to first form the amide linkages prior to polymerization. This can be accomplished by combining about two moles of glycolic or lactic acid 25 with about one mole of a diamine and heating at a temperature between 150° to 220°C until distillation of water is complete. Alternatively, combination of hydroxy acid and diamine will produce a salt which can be purified by recrystallization and then subjected to the above condensation. In either case, a high yield of diamidediol is obtained which can be purified by recrystallization.

Diamidediols useful in synthesizing polymers of this invention can be prepared by the above 30 methods from diamines such as 1,2-ethanediamine; 1,3-propanediamine; 1,3-(2-methylpropane)-diamine; 1,3-(2,2-dimethylpropane)diamine; 1,2-(1,2-dimethylethane)diamine; 1,4-butanediamine; 1,5-pentanediamine; 1,6-hexanediamine; 1,7-heptanediamine; 1,8-octanediamine; 1,9-nonanediamine; 1,10-decanediamine; 1,11-undecanediamine; 1,12-dodecanediamine; 1,13-tridecanediamine; 1,14-tetradecanediamine; 1,15-pentadecanediamine; 1,16-hexadecanediamine; 3-oxapentane-1,5diamine; 4-oxaheptane-1,7-diamine; 5-oxanonane-1,9-diamine; 6-oxaundecane-1,11-diamine; 7-oxatridecane-1,13-diamine; 8-oxapentadecane-1,15-diamine; 9-oxaheptadecane-1,17-diamine; 10-oxanonadecane-1,19-diamine; 11-oxaheneicosane-1,21-diamine; 12-oxatricosane-1,23-diamine; 13-oxapentacosane-1,25-diamine; 4,9-dioxadodecane-1,12-diamine; 3,6-dioxaoctane-1,8-diamine and other analogs of oxa-aliphatic diamines and the corresponding thia-aliphatic diamines; 40 cyclohexane-1,4-diamine; cyclohexane-1,3-diamine; cyclohexane-1,2-diamine; 1,4-bis(aminomethyl)-cyclohexane; 1,3-bis(aminomethyl)cyclohexane; 1,4-bis(2-aminoethyl)cyclohexane; 1,4-bis(3-amino-propyl)cyclohexane; bis(4-aminocyclohexyl)methane; *p*-phenylenediamine; *o*-phenylenediamine; *m*-phenylenediamine; *p*-xylylene- α,α' -diamine and other aromatic diamines; piperazine; 4,4'-trimethylenedipiperidine; 4,4'-bipiperidine; N,N'-bis(3-aminopropyl)piperazine; 2,5-dimethylpiperazine; 45 2,6-dimethylpiperazine; 2-methylpiperazine; imidazolidine; 2-methylimidazolidine; 4,5-dimethylimida-zolidine.

In the preferred body absorbable polymeric material, it is preferred that the diamidediols be a mixture of 1,12-di(hydroxyacetamido)-4,9-dioxadodecane and 1,12-di(hydroxyacetamido)dodecane, with groups R¹, R², R³, and R⁴ being formed by the removal of the elements of water in the condensa- 50 tion of glycolic acid with 4, 9,-dioxo-1,12-doce-canediamine and 1,12-dodecanediamine.

Synthesis of the body-absorbable polymer of the present invention can be accomplished by any of a number of well known techniques. For example, the diamidediol can be combined with an equimolar amount of one or more dicarboxylic acids or dicarboxylic acid methyl esters and appropriate esterifica- 55 tion catalyst, e.g. Sb₂O₃, and heated with stirring under nitrogen at temperatures of 150° to 250°C for 10 to 100 hours with 175° to 200°C for 20 to 40 hours being preferred.

A preferred method of preparing polymer consists of dissolving the diamidediol in a solvent which is nonreactive with acid chlorides and has a boiling point of 100°C or higher, heating the mixture to reflux, and rapidly adding an equimolar amount of a diacid chloride with vigorous mechanical mixing (e.g., motor-driven paddle) separating the polymer from solvent and drying the polymer at temperatures 60 below the melting point of the polymer. Suitable solvents include methylchloroacetate, chlorobenzene 1,1,2-tri-chloroethane or 1,4-dioxane. The preferred solvent for uses with a diacid chloride is chlorobenzene.

The preferred method has the advantages of not requiring catalyst, of yielding product in a relatively short period of time, and producing high molecular weight polymer in a granular, easy-to- 65 manipulate form. In addition, moisture which would otherwise react with the acid chloride can be

readily excluded from the system by azeotropic distillation prior to addition of the diacid chloride. Polymer prepared by this method can be further improved with respect to increasing the molecular weight by heating for several days under partial vacuum with a stream of dry nitrogen passing over the polymer at temperatures that are 10° to 50°C below the polymer melting temperature.

5 Dicarboxylic acid chlorides and the diacid dimethyl or diethyl esters of dicarboxylic acids useful in the synthesis of polymers by the above methods include those derived from the dicarboxylic acids listed below. In addition, the free acids can also be used. The term "dicarboxylic acid" as used herein includes dicarboxylic acids, their methyl and ethyl esters, their acid chlorides and anhydrides. They are, for example, oxalic acid; malonic acid; succinic acid; 2,3-dimethylsuccinic acid; glutaric acid; 3,3-dimethyl-
10 glutaric acid; 3-methyladipic acid; adipic acid; pimelic acid; suberic acid; azelaic acid; sebacic acid; 1,9-nonanedicarboxylic acid; 1,10-decanedicarboxylic acid; 1,11-undecanedicarboxylic acid; 1,12-dodecanedicarboxylic acid; 1,13-tridecanedicarboxylic acid; 1,14-tetradecanedicarboxylic acid; 1,15-pentadecanedicarboxylic acid; 1,16-hexadecanedicarboxylic acid; maleic acid; *trans*- β -hydromuconic acid; fumaric acid; diglycolic acid; 3,3'-oxydipropionic acid; 4,4'-oxydibutyric acid; 5,5'-oxydivaleric acid; 6,6'-oxydicaproic acid; 8,8'-oxydicaprylic acid; 6-oxaundecanedioic acid; 5-oxaazelaic acid; 5-
15 oxasebacic acid; 5-oxaundecanedioic acid; 5-oxadodecanedioic acid; 5-oxatetradecanedioic acid; 5-oxahexadecanedioic acid; 6-oxadodecanedioic acid; 6-oxatridecanedioic acid; 6-oxapentadecanedioic acid; 6-oxaheptadecanedioic acid; 7-oxapentadecanedioic acid; 10-oxanonadecanedioic acid and other oxa-aliphatic dicarboxylic acids; phthalic acid; isophthalic acid; terephthalic acid and other aromatic dicarboxylic acids; 1,2-cyclobutanedicarboxylic acid; 1,4-cyclohexanedicarboxylic acid. In the preferred
20 body-absorbable polymeric material, R⁵ is preferably ethylene, being formed by the removal of the chloride from succinyl chloride.

Polymers can also be prepared by reaction of the diamidediols with bischloroformates. The bischloroformates, in turn, can be prepared by reacting a dihydroxy compound with excess phosgene
25 gas in the condensed phase or in solution (see *Preparative Methods of Polymer Chemistry, 2nd Ed.*, Sorenson and Campbell, Interscience Publishers (1968), p. 123). Dihydroxy compounds that can be used include, for example, the previously mentioned diamidediols; ethylene glycol; 1,3-propanediol; 1,4-butanediol; 1,5-pentanediol; 1,6-hexanediol; 1,7-heptanediol; 1,8-octanediol; 1,9-nonanediol; 1,10-decanediol; 1,11-undecanediol; 1,12-dodecanediol; 1,13-tridecanediol; 1,14-tetradecanediol; 1,15-pentadecanediol; 1,16-hexadecanediol; oxaaliphatic diols and poly(ethyleneoxy)diols of various
30 molecular weights.

The polymeric materials of this invention can be fabricated into films and fibers by melt-extrusion. When the polymers are fabricated into fibers, it is preferred that n of the general formula have an average value from about 30 to about 50. Such fibers have been implanted subcutaneously in mice and
35 have been found to be non-irritating and compatible with the living tissue over the time span of many months. After approximately eight months, a substantial amount of the polymer has been absorbed by the living tissue.

The polymers of the present invention are also useful in the manufacture of cast and/or extruded films and molded solid surgical aids. Thus, cylindrical pins, screws, reinforcing plates, etc., may be
40 machined from the cast or molded polymer having the aforementioned *in vivo* absorption characteristics.

The preparation of the body-absorbable polymeric material of the present invention may be further illustrated by reference to the following examples:

Example 1

45 1. Synthesis of 1,12-di(hydroxyacetamido)dodecane.
Two moles of vacuum redistilled 1,12-dodecanediamine (400 g) were dissolved in 5 liters of isopropyl alcohol in a 6-liter stainless steel beaker and four moles of glycolic acid (304 g) were added carefully in small portions with stirring. The resultant solution was covered with aluminum foil and
50 allowed to cool gradually to room temperature whereupon formation of a white crystalline solid occurred. The crystals were collected on a large Buchner funnel, rinsed with isopropanol, and air dried yielding 647 g (92%), m.p. 94—97°C.

The solid was placed in a 5-liter round-bottom 3-neck flask and heated in a large oil bath with overhead stirring. A stream of dry nitrogen was passed into the system and through the attached
55 distillation apparatus. The melted solid was heated to 190°C at which temperature vigorous distillation of water occurred. After 4 hours evolution of water had subsided completely and the liquid was poured into metal pans where it rapidly solidified. The product was recrystallized from 6 liters of absolute methanol to yield 530 g (84%) of lustrous white crystals; m.p. 127—130°C; infrared ("Nujol") 1650 cm⁻¹, 3250 cm⁻¹; proton nuclear magnetic resonance (DMSO-d₆/TMS, 100 MHz) δ 1.27 (singlet, 20 protons), δ 3.13 (quadruplet, 4 protons), δ 3.82 (doublet, 4 protons), δ 5.47 (triplet, 2 protons), and
60 δ 7.73 (broad triplet, 2 protons).

2. Synthesis of poly[dodecane-1,12-di(carbonyloxy)dodecane-1,12-di(amidocarbonylmethylene)].

Exactly 486.3 g (1.54 moles) of 1,12-di(hydroxyacetamido)dodecane and 397.0 g (1.54 moles)
65 of 1,12-dodecanedicarboxylic acid were melted together in a 2-liter glass resin flask heated in an oil

bath. Overhead stirring of the molten mixture was commenced and 0.8 g of "Irganox" 1010 (a phenolic antioxidant available from Ciba-Geigy) (Irganox is a trade mark) added. Dry nitrogen was admitted through a tube reaching below the surface of the liquid. The mixture was heated at 175°C for 20 hours, during which time distillation of water occurred. Antimony trioxide (0.8 g) was added and heating and stirring were continued for an additional 16 hours at 200°C. The viscous, light brown colored product was poured out and allowed to solidify. The solid was dissolved in 15 liters of boiling isopropanol and the solution allowed to cool to 30°C at which temperature the precipitated solid was collected and dried to yield 525 g of powder; inherent viscosity 0.26 (0.5% in 1,1,1-trifluoroethanol (hereinafter designated TFE) at 30°C); differential thermal analysis, $T_g = -1$ to $+20^\circ\text{C}$, $T_m = 93^\circ\text{C}$. (T_g is the glass transition temperature, T_m is the melting point of the polymer)

3. *In vivo* evaluation.

The above polymer was melt-extruded in a 3/4 inch Brabender extruder equipped with 30:1 length:diameter ratio general purpose screw and oriented at a temperature above its glass transition temperature by drawing at a ratio between about 4 to 1 and 10 to 1 to produce uniform fiber with a tenacity of 2.5 g/denier. The fiber was cut into 20-cm lengths which were alternately assigned to control and experimental groups. All fiber was handled the same with respect to ethylene oxide sterilization and drying. The experimental fibers were surgically implanted subcutaneously in mice. The mice were necropsied at various time intervals and the tensile strength of recovered fiber measured after drying and compared with control samples. The data recorded in Table 1 were obtained by averaging 8 to 10 individual values recorded at each time period.

TABLE 1

	Days Post Implantation	Tensile Strength Retained
	5	46.6%
	7	28.0%
	14	12.3%

Additional fiber-implanted mice were necropsied at monthly intervals. After two months the fibers possessed virtually no physical integrity, were broken into small pieces approximately 1 to 2 mm in length, and were encapsulated. By six months only a trace of the polymer could be detected visually, the majority having been completely absorbed. In all of these evaluations there was no visible reaction to the surrounding tissue and no evidence of toxicity.

Example 2

Alternate synthesis of poly[dodecane-1,12-di(carboxyloxy)dodecane-1,12-di(amidocarbonylmethylene)].

Dimethyl-1,12-dodecanedicarboxylate (19.72 g, 0.069 mole) and 1,12-di(hydroxyacetamido)-dodecane (21.79 g, 0.069 mole) prepared according to the procedure in Example 1 were placed in a 250-ml round-bottom 3-neck flask and heated in an oil bath with overhead stirring. About 10 mg each of "Irganox" 1010 and zinc acetate were added and the mixture heated to 185°C, with dry nitrogen passing over the reactants and through the attached distillation apparatus. Heating and stirring were continued for 20 hours at 170—185°C. Antimony trioxide (about 10 mg) was added and the temperature maintained at 190—200°C for an additional 20 hours. During this time the melt increased in viscosity and high vacuum was applied intermittently. The dark brown product was allowed to cool and was then dissolved in hot isopropyl alcohol (1 liter). The isopropyl alcohol solution was allowed to cool to 30°C, at which temperature the precipitated solid was collected and dried to yield 30.1 g of powder; inherent viscosity 0.27 (0.5% in TFE at 30°C); differential thermal analysis, $T_g = +3$ to $+24^\circ\text{C}$, $T_m = 117^\circ\text{C}$.

The powdered polymer was placed in a glass U-tube and heated in an oil bath for 60 hours at 97°C. During this time a slow stream of dry nitrogen was passed through the polymer which remained in the solid state. As a result of this treatment the inherent viscosity increased significantly to 0.36. Filaments pulled from the melted polymer were easily cold drawn by hand to yield tenacious fibers.

Example 3

1. Synthesis of poly[oxysebacoyloxydodecane 1,12-di(amidocarbonylmethylene)].

Exactly 404.7 g (1.28 moles) of 1,12-di(hydroxyacetamido)dodecane prepared according to the procedure in Example 1 and 258.5 g (1.28 moles) of sebacic acid were melted together in a 2-liter

glass resin flask heated in an oil bath. Overhead stirring was commenced and 0.6 g of "Irganox" 1010 antioxidant added. Dry nitrogen was admitted through a tube reaching below the surface of the liquid. The mixture was heated at 175°C for 20 hours during which time distillation of water occurred. 0.6 g of antimony trioxide was added and heating and stirring continued for an additional 20 hours at 190°C. Nitrogen flow was discontinued, the system was placed under vacuum of about 0.1 Torr, and heating and stirring continued for 4 hours at 210°C. The reaction was then discontinued and the viscous, brown liquid poured into a metal pan where it solidified into a hard, tough solid. The solid was dissolved in 3 liters of boiling isopropanol and the solution poured slowly into 4 liters of acetone with vigorous stirring. The resultant precipitate was collected and dried to yield 430 g of powder; inherent viscosity 0.32 (0.5% in TFE at 30°C); differential analysis, $T_g = -10$ to $+9$, $T_m = 50^\circ\text{C}$.

2. *In vivo* evaluation.

The above polymer was melt extruded and oriented as in Example 1 to produce uniform fiber with a tenacity of 0.82 g/denier. The fiber was implanted in mice as described in Example 1. The strength loss results are shown in Table 2.

TABLE 2

	Days Post Implantation	Tensile Strength Retained
	3	61.4%
	10	18.8%

The implantation site in each of the mice showed no visible inflammation or other evidence of an adverse reaction toward the polymer.

Example 4

1. Synthesis of 1,10-di(hydroxyacetamido)decane.

1,10-decanediamine (10 g, 0.58 mole) was dissolved in 150 ml of boiling isopropanol and solid glycolic acid (8.8 g, 0.116 mole) added in portions with stirring. An oil that separated from the cooled solution rapidly crystallized upon scratching. Recrystallization from isopropanol yielded white crystals (16.3 g, 87% yield, m.p. 57–62°C).

The 1,10-decanediammonium glycolate was placed in a 3-neck 100-ml round-bottom flask and heated in an oil bath with magnetic stirring. Dry nitrogen was passed over the melted solid and through the attached distillation apparatus. Distillation of water occurred at 150°C. After 4 hours at 150–165°C, no further evolution of water could be detected and the liquid was poured into a dish, where it rapidly solidified. Recrystallization from methanol gave 10.7 g (74%) of white crystals; m.p. 120–122°C.

2. Synthesis of poly[decane-1,10-di(carboxyloxy)decane-1,10-di(amidocarbonylmethylene)].

Exactly 9.50 g (0.033 mole) of 1,10-di(hydroxyacetamido)decane and 7.66 g (0.033 mole) of 1,10-decanedicarboxylic acid were placed in a 100-ml round-bottom flask and heated in an oil bath with overhead stirring. "Irganox" 1010 antioxidant (about 5 mg) was added and the mixture heated to 170°C with dry nitrogen passing over the reactants and through the attached distillation apparatus. Heating and stirring were continued overnight (16 hours) at 170°C. Antimony trioxide (about 5 mg) was added and the temperature increased to 190–210°C for 8 hours. During this time the melt became rather viscous and a vacuum of about 0.1 Torr was applied intermittently. The melt was allowed to cool completely overnight and was then reheated to 210°C for 2 hours followed by an additional 30 minutes under vacuum. The viscous, amber colored product was poured onto a metal surface where it cooled to form a tough solid; inherent viscosity 0.26 (0.5% in TFE at 30°C); differential thermal analysis, $T_g = -8$ to $+2^\circ\text{C}$, $T_m = 51^\circ\text{C}$. Filaments pulled from the melted polymer were easily cold drawn by hand to yield tenacious fibers.

Example 5

1. Synthesis of poly[oxysuccinoyloxylododecane 1,12-di(amidocarbonylmethylene)].

Exactly 390.4 g (1.235 moles) of 1,12-di(hydroxyacetamido)dodecane prepared according to the procedure in Example 1 and 1 kg of chlorobenzene were placed in a 3-liter resin flask and heated in an oil bath with overhead stirring. The solid dissolved and approximately 200 ml of chlorobenzene was distilled from the solution. The solution was allowed to cool to 120°C and the distillation apparatus was replaced with a reflux condenser connected to gas washing bottles, the first empty and the second filled with water. Vacuum-redistilled succinyl chloride (191.5 g, 1.235 moles) was added cautiously through an addition funnel to the solution while stirring at approximately 300 rpm. The exothermic

reaction was accompanied by vigorous evolution of hydrogen chloride gas. Approximately 20 minutes after addition of succinyl chloride, the solution became viscous and the polymer solidified and separated from the solution. The mixture was refluxed with stirring for an additional 2 hours during which time the evolution of hydrogen chloride subsided. The chlorobenzene was removed by distillation under reduced pressure to yield 490 g of product; inherent viscosity 0.45 (0.5% in TFE at 30°C); differential thermal analysis, $T_g = +16$ to $+48^\circ\text{C}$, $T_m = 160^\circ\text{C}$.

The product was placed in a 3-neck flask and heated in an oil bath for 48 hours at 130°C . During this time a slow stream of dry nitrogen was passed through the polymer which remained in the solid state. As a result of this treatment the inherent viscosity increased significantly to 0.81.

10

2. *In vivo* evaluation

The above polymer was melt-extruded and oriented as in Example 1 to product uniform fiber corresponding to U.S.P suture size number 00 with a tenacity of 2.4 g/denier. Two commercial U.S.P. number 00 absorbable sutures, "Vicryl" (Ethicon, Inc.) and chromic catgut (Ethicon, Inc.) were purchased and included in the evaluation. Vicryl (trade mark) is a commercially available material purchased from Ethicon Inc. This material is described in Gilding, D.K., et al., "Biodegradable polymers for use in surgery-polyglycolic/poly(lactic acid) homo- and copolymers:1," *Polymer* 20, 1459 (1979). The tensile strength of the material as tested by Applicant was 5.2 g/denier. The *in vivo* fiber strength retention data was obtained as described in Example 1 and is shown in the accompanying figure. The following designations are used: "Vicryl" (A), chromic catgut (B), polymer of Example 5 (C), and polymer of Example 14 (D).

The strength loss profile of fiber produced in this example illustrates that this polymer should be useful clinically where approximation of healing tissue is required for a longer period of time than can presently be achieved with currently available absorbable sutures.

The implantation site revealed no evidence of irritation or incompatibility in each of the necropsies involving the above polymer. This was not the case with chromic catgut, however, which produced inflammatory reactions varying from slight to massive.

Example 6

1. Synthesis of 4,4'-methylenebis(hydroxyacetamidocyclohexane).

4,4'-Methylenebis(cyclohexylamine) (56.5 g, 0.27 mole) was dissolved in hot isopropanol (500 ml) and glycolic acid (40.9 g, 0.54 mole) added portion-wise with stirring. Upon cooling, a white gummy solid separated which was isolated by decantation and redissolved in a small volume of ethanol. Crystallization produced a white crystalline, deliquescent solid; m.p. $96-102^\circ\text{C}$. Thorough drying under vacuum increased the melting point (m.p. $149-151^\circ\text{C}$) and reduced the deliquescence.

The solid was placed in a 250 ml-round-bottom flask and heated in an oil bath with stirring. Distillation of water occurred at 150°C and the temperature was increased to 175°C . After stirring at 175°C for 3 hours the melt suddenly resolidified into a white crystalline mass. The solid was recrystallized from a mixture of ethanol and methanol to yield lustrous, white crystals, m.p. $208-211^\circ\text{C}$; infrared ("Nujol"), 1630 cm^{-1} , 3250 cm^{-1} ; proton nuclear magnetic resonance (CDCl_3/TMS , 100 MHz), δ 0.6—1.5 (complex multiplet, 12 protons), δ 1.5—1.8 (doublet, 8 protons), δ 3.50 (broad singlet, 2 protons), δ 3.75 (doublet, 4 protons), δ 5.35 (triplet, 2 protons), δ 7.37 (doublet, 2 protons).

2. Alternate synthesis of 4,4'-methylenebis(hydroxyacetamidocyclohexane).

4,4'-Methylenebis(cyclohexylamine) (25 g, 0.12 mole) and glycolic acid (18.2 g, 0.24 mole) were combined in a 250-ml round-bottom flask heated in an oil bath. The solids were melted together with mixing and heated to 175°C whereupon distillation of water occurred. After heating for 3 hours the evolution of water subsided and crystallization commenced. The solid was removed and recrystallized from methanol to yield 34 g (87%) of lustrous white needles; m.p. $208-212^\circ\text{C}$.

3. Synthesis of poly[decane-1,10-di(carbonyloxy)dicyclohexylmethane-4,4'-di(amidocarbonylmethylene)].

Exactly 1.748 g (0.0065 mole) of 1,10-decanedicarbonyl chloride was placed in a 100-ml round-bottom flask and dissolved in chlorobenzene (20 ml). 4,4'-methylenebis(hydroxyacetamidocyclohexane) (2.120 g, 0.0065 mole) was added and the mixture heated to reflux with stirring. Vigorous evolution of hydrogen chloride occurred, and after refluxing for approximately 30 minutes the mixture became a clear, colorless solution.

Refluxing was continued for 2 hours and the solution then allowed to cool whereupon precipitation occurred. The precipitate was collected by filtration and dried under vacuum to give a white powder; inherent viscosity (0.5% in TFE at 30°C) of 0.35; differential thermal analysis, $T_g = +75^\circ$ to $+85^\circ\text{C}$, $T_m = 185^\circ\text{C}$. Filaments pulled from the melted polymer were easily cold drawn by hand to give tenacious fibers.

65

Example 7

Synthesis of poly[ethane-1,2,-di(oxy-carbonyloxy)dicyclohexylmethane-4,4'-di(amidocarbonylmethylene)].

Exactly 5.643 g (0.0301 mole) of vacuum redistilled ethylene bischloroformate were placed in a 50 ml round-bottom flask and 20 ml of chlorobenzene added followed by 9.837 g (0.0301 mole) of 4,4'-methylenebis(hydroxyacetamidocyclohexane) prepared according to the procedure in Example 6. The mixture was heated in an oil bath to 130°C with rapid magnetic stirring. Vigorous evolution of hydrogen chloride gas occurred and the mixture turned dark yellow in color. After refluxing the mixture for 2 hours, the solid was collected by filtration and dried under vacuum to yield a light tan colored powder; inherent viscosity 0.09 (0.5% in TFE at 30°C); infrared ("Nujol"), 1650 cm⁻¹, 1750 cm⁻¹; differential thermal analysis, T_g = +70 to +84°C, T_m = 180°C with decomposition.

Example 8

1. Synthesis of *trans*-1,4-cyclohexanebis(hydroxyacetamidomethyl).

Glycolic acid (313 g, 4.12 moles) was dissolved in 2 liters of absolute methanol and a methanolic solution of 1,4-cyclohexanebis(methylamine) (291 g, 2.05 moles, approximately 20% *cis* and 80% *trans* isomers) added carefully with stirring. The hot solution was boiled for 3 to 5 minutes and then cooled slowly to 4°C whereupon crystallization occurred. The white, crystalline product was collected on a Buchner funnel, rinsed with methanol, and dried under vacuum at 60°C to yield 541 g (89.5%); m.p. 199—201°C.

The glycolic acid salt was placed in a 3-liter 3-neck round-bottom flask heated in an oil bath with mechanical stirring. Dry nitrogen was passed into the system and through the attached distillation apparatus. Upon heating to 210°C, vigorous distillation of water occurred and subsided completely after 45 minutes. 73.8 g (99.5%) of water were collected. The solidified product was dissolved in 6 liters of hot absolute ethanol and allowed to cool slowly to room temperature whereupon crystallization occurred. The clusters of long, pale yellow colored needles which formed were collected and dried to yield 273 g (51.4%); m.p. 182—186°C; infrared ("Nujol"), 1625 cm⁻¹, 3270 cm⁻¹; proton nuclear magnetic resonance (DMSO-d₆/TMS, 100 MHz), δ 0.6—1.9 (complex multiplet, 10 protons), δ 2.98 (triplet, 4 protons), δ 3.83 (doublet, 4 protons), δ 5.44 (triplet, 2 protons), δ 7.67 (triplet, 2 protons).

The filtrate was concentrated to a volume of 2 liters and cooled to -20°C whereupon a powdery white solid appeared. The solid was collected and dried to yield 104 g (19.6%); m.p. 136—142°C. The proton nuclear magnetic resonance spectrum for this material is essentially the same as above except that the multiplet at δ 3.0 is more complex and the multiplet at δ 0.6—1.9 is partially replaced by a singlet occurring at δ 1.35. It is estimated that this lower melting fraction is approximately 40% *trans* and 60% *cis* isomers of the desired product whereas the higher melting major fraction is virtually pure *trans* isomer. It is believed that fractional crystallization is possible due to the fact that the *cis* isomer can form intramolecular hydrogen bonds whereas the *trans* isomer cannot.

2. Synthesis of poly[*trans*-oxysebacoyloxycyclohexane-1,4-di(methylene amidocarbonylmethylene)].

186.0 g (0.721 mole) of *trans*-1,4-cyclohexanebis(hydroxyacetamidomethyl) were placed in a 3-liter 3-neck round-bottom flask and 800 g of chlorobenzene added. The mixture was heated with overhead stirring and approximately 150 ml of chlorobenzene distilled from the solution. The distillation apparatus was then replaced with a reflux condenser as in Example 5. Vacuum redistilled sebacoyl chloride (172.3 g, 0.721 mole) was added carefully through an addition funnel with rapid stirring. Vigorous evolution of hydrogen chloride gas occurred and the product separated as a granular solid. The mixture was refluxed for 2 hours during which time evolution of hydrogen chloride gas subsided. Filtration while hot and drying under vacuum yielded 208 g of powder; inherent viscosity 0.60 (0.5% in TFE at 30°C); differential thermal analysis, T_g = +50 to +57°C, T_m = 180°C.

The polymer was melt-extruded and oriented as in Example 1 to produce uniform fiber with a tenacity of 1.70 g/denier.

Example 9

1. Synthesis of N,N'-di(hydroxyacetyl)-piperazine.

Piperazine hexahydrate (17.5 g, 0.090 mole) was dissolved in 1 liter of absolute methanol and solid glycolic acid (13.7 g, 0.180 mole) added with stirring. The solution was boiled for a few minutes and then allowed to cool slowly. Crystallization produced long, white needles which were collected and dried under vacuum to give 16.3 g (76%); m.p. 169—173°C. The product was placed in a 100-ml round-bottom flask and heated in an oil bath with magnetic stirring. A stream of dry nitrogen was passed through the system and the temperature maintained at 180—190°C for 3 hours. After distillation of water subsided, the liquid was solidified and recrystallized from 1 liter of absolute ethanol to give a white powder; m.p. 187—190°C; infrared ("Nujol"), 1625 cm⁻¹, 3250 cm⁻¹; proton nuclear magnetic resonance (DMSO-d₆/TMS, 100 MHz), δ 3.43 (singlet, 8 protons), δ 4.12 (singlet, 4 protons), δ 4.63 (broad singlet, 2 protons).

2. Synthesis of poly(oxy succinoyloxy)piperazine N,N'-di(carbonylmethylene).

N,N'-di(hydroxyacetyl)piperazine (2.70 g, 0.0133 mole) was placed in a 50-ml round-bottom flask and 15 ml of chlorobenzene added. The mixture was stirred magnetically and vacuum redistilled succinyl chloride (2.07 g, 0.0133 mole) added. The mixture was heated in an oil bath at 120—130°C for 3 hours during which time evolution of hydrogen chloride gas occurred. The product was collected by filtration and dried under vacuum to yield a tan colored powder; inherent viscosity 0.14 (0.5% in TFE at 30°C); differential thermal analysis, $T_g = +55$, to $+75^\circ\text{C}$, $T_m = 200^\circ\text{C}$ with decomposition.

Example 10

1. Synthesis of 1,12-di(hydroxyacetamido)-4,9-dioxadodecane.

4,9-Dioxadodecane-1,12-diamine (22.8 g, 0.112 mole) was placed in a 250-ml round-bottom flask and glycolic acid (17.0 g, 0.224 mole) added in portions with stirring and cooling. The resultant liquid was heated in an oil bath to 185°C whereupon distillation of water occurred. Heating was continued at 185° to 195°C for 2 hours after which time distillation of water subsided and the liquid was poured into a crystallization dish. The resultant oil slowly crystallized in the form of large white clusters; yield 35.5 g (99.3%); m.p. 67—71°C. The solid was recrystallized from cold absolute methanol to give a white, crystalline product; m.p. 74—77°C; infrared ("Nujol"), 1120 cm^{-1} , 1625 cm^{-1} , 3250 cm^{-1} ; proton nuclear magnetic resonance (CDCl_3/TMS , 100 MHz), δ 1.55—1.95 (complex multiplet, 8 protons), δ 3.30—3.65 (complex multiplet, 12 protons), δ 4.03 (singlet, 4 protons), δ 4.98 (broad singlet, 2 protons), δ 7.51 (broad triplet 2 protons).

2. Synthesis of poly[oxy succinoyloxy-4,9-dioxadodecane-1,12-di(amidocarbonylmethylene)].

Redistilled succinyl chloride (5.437 g, 0.035 mole) was placed in a 100-ml round-bottom flask and diluted with chlorobenzene (40 ml). The solution was stirred magnetically and 1,12-di(hydroxyacetamido)-4,9-dioxadodecane (11.224 g, 0.035 mole) added. The mixture was heated in an oil bath to 50°C whereupon evolution of hydrogen chloride gas commenced and an oily layer separated. The mixture was refluxed for 2 hours and then allowed to cool. The solidified product was collected and dried under vacuum at 50°C to give a waxy material; inherent viscosity 0.16 (0.5% in TFE at 30°C); differential thermal analysis, $T_g = -11^\circ$ to -4°C , $T_m = 72^\circ\text{C}$.

Example 11

1. Synthesis of poly[oxy succinoyloxydodecane-1,12-di(amidocarbonylmethylene)-co-10%-oxy succinoyloxy-4,9-dioxadodecane-1,12-di(amidocarbonylmethylene)].

Exactly 457.8 g (1.449 moles) of 1,12-di(hydroxyacetamido)dodecane prepared according to the procedure in Example 1 and 51.5 g (0.161 mole) of 1,12-di(hydroxyacetamido)-4,9-dioxadodecane prepared according to the procedure in Example 10 were placed in a 5-liter resin flask and 1.5 kg of chlorobenzene added. The reaction was conducted as described in Example 5. After distillation of approximately 200 ml of chlorobenzene, 249.5 g (1.610 moles) of redistilled succinyl chloride was added through an addition funnel to the rapidly stirring solution. Approximately 20 minutes after addition of succinyl chloride, the solution became viscous and the polymer soon solidified and separated from the solution. The mixture was refluxed with stirring for an additional 2 hours during which time the evolution of hydrogen chloride subsided. The product was collected by filtration and dried under vacuum at 100°C to yield 524 g of powder; inherent viscosity 0.31 (0.5% in TFE at 30°C); differential thermal analysis, $T_g = +16$ to $+38^\circ\text{C}$, $T_m = 135^\circ\text{C}$.

The product was placed in a dish and heated in a vacuum oven for 6 days at 128°C under partial vacuum. During this time a slow stream of dry nitrogen was passed over the polymer which remained in the solid state. As a result of this treatment the inherent viscosity increased significantly to 0.48.

2. Fiber evaluation.

The above polymer was melt-extruded and oriented as described in Example 1 to produce uniform fiber with a tenacity of 1.93 g/denier, 43% elongation, and modulus of 1.37. This fiber is noticeably more flexible than the fiber prepared from homopolymer in Example 5.

Example 12

55 Synthesis of poly[3-oxapentane-1,5-di(carbonyloxy)dodecane-1,12-di(amidocarbonylmethylene)].

Anhydrous dioxane (250 ml) and 1,12-di(hydroxyacetamido)dodecane (46.9 g, 0.148 mole) prepared according to the procedure in Example 1 were placed in a 500-ml round-bottom flask and heated under reflux with overhead mechanical stirring. Redistilled diglycyl chloride (25.4 g, 0.148 mole) was added cautiously through an addition funnel to the refluxing solution. The hydrogen chloride gas which evolved was entrained in a stream of dry nitrogen and trapped in a water filled gas washing bottle. An oily layer soon separated from the solution and refluxing was continued for 4 hours. The mixture was then allowed to cool and the solidified material collected and dried under vacuum to give 67.4 g of product; inherent viscosity 0.23 (0.5% in TFE at 30°C); differential thermal analysis, $T_g = +19^\circ$ to $+53^\circ\text{C}$, $T_m = 124^\circ\text{C}$.

65 The polymer was placed in a U-shaped tube and heated in an oil bath at 100° to 115°C for 5

days. During this time a slow stream of dry nitrogen was passed through the polymer which remained in the solid state. As a result of this treatment the inherent viscosity increased significantly to 0.34. Filaments pulled from the melted polymer were easily cold drawn by hand to give tenacious fiber.

Example 13

1. Synthesis of 4,4'-methylenebis(α -hydroxypropionamidocyclohexane).

Molten 4,4'-methylenebis(cyclohexylamine) (224.0 g, 1.065 moles) was placed in a 1-liter round-bottom flask and 85% lactic acid (225.5 g, 2.13 moles) added slowly through an addition funnel with stirring and cooling. The resultant liquid was then heated in an oil bath to 190°C whereupon distillation of water occurred. Heating was continued at 190°C for 4 hours after which time distillation of water subsided and the liquid was poured into a Pyrex baking dish. Upon cooling the product solidified into a clear, amber colored glass. The solid was broken up and recrystallized twice from tetrahydrofuran containing 10% methanol to give lustrous, white flakes; m.p. 195—199°C; infrared ("Nujol"), 1640 cm^{-1} , 3300 cm^{-1} ; proton nuclear magnetic resonance (DMSO- d_6 /TMS, 100 MHz), δ 0.6—1.5 (complex multiplet with doublet superimposed at δ 1.15, 18 protons), δ 1.5—1.8 (doublet, 8 protons), δ 3.50 (broad singlet, 2 protons), δ 3.7—4.1 (multiplet, 2 protons), δ 5.35 (doublet, 2 protons), δ 7.30 (doublet, 2 protons).

2. Synthesis of poly[oxysebacoyloxycyclohexane-1,4-di(amidocarbonylethylidene)].

Exactly 86.0 g (0.2427 mole) of 4,4'-methylenebis(hydroxypropionamidocyclohexane) were placed in a 1-liter 3-neck round-bottom flask and 600 ml of chlorobenzene added. The mixture was heated with overhead stirring and approximately 50 ml of chlorobenzene distilled. The solid remained undissolved and formed a thick suspension. Vacuum redistilled sebacoyl chloride (58.0 g, 0.2427 mole) was added carefully through an addition funnel with rapid stirring. This caused the diamidediol to dissolve and form a clear, colorless solution. The heating and stirring were continued for 45 minutes during which time HCl evolved and the solution viscosity increased markedly. The solvent was then removed by distillation under reduced pressure and the resulting solid product kept under high vacuum overnight at 115°C. Upon cooling, the flask broke in numerous places. This polymer gave no adhesive failure with the glass flask which had to be removed by pulverization. The polymer is a hard, tough, colorless, thermoplastic solid which can be cold drawn to give strong, rigid filaments; inherent viscosity 1.17 (0.5% in TFE at 30°C); differential thermal analysis, $T_g = +90$ to 100°C, $T_m = 199^\circ\text{C}$.

Example 14

1. Synthesis of poly[oxy succinoyloxy dodecane-1,12-di(amidocarbonylmethylene)-co-10%-oxy succinoyloxy-4,9-dioxadecane-1,12-di(amidocarbonylmethylene)].

A ten-gallon glass-lined reaction kettle equipped with a reflux condenser, pyrometer, addition funnel, and dry nitrogen purge was charged with exactly 1,942.4 g (6.15 moles) of 1,12-di(hydroxyacetamido)dodecane prepared according to the procedure in Example 1, 218.6 g (0.68 moles) of 1,12-di(hydroxyacetamido)-4,9-dioxadodecane prepared according to the procedure in Example 10, and 6 gallons of chlorobenzene. The reaction kettle was heated by means of a steam jacket to 130°C for 30 minutes with stirring to insure complete dissolution of the diamidediol monomers. The temperature was then stabilized at 125°C and the stirring speed increased to the maximum setting. Exactly 1,058.6 g (6.83 moles) of vacuum redistilled succinyl chloride was added through the addition funnel at a constant rate during the time course of 3 minutes and 40 seconds. Stirring and heating were continued at 125°C for 30 minutes after which time the stirring rate was decreased and the reactor allowed to cool to room temperature. The granular product was collected on a large ceramic filter, rinsed with heptane, and placed in a vacuum oven at 100°C. After drying for 2 days the inherent viscosity was 0.92 (0.5% in TFE at 30°C) and increased to 1.03 after heating in the oven under partial vacuum and a slow stream of dry nitrogen for an additional 4 days at 120°C.

2. Fiber evaluation.

The above polymer was melt-extruded and oriented as described in Example 1 to produce 2—0 suture size fiber with a tenacity of 6.53 g/denier, 34.8% elongation, and modulus of 20.6 g/denier. The number of throws for the interlacement of the parts to hold a surgeon's knot is two, the minimum possible number, and the knot strength is 47.5% of the tensile strength. By "knot strength" is meant the tensile strength of a knotted suture as determined by the method specified in *United States Pharmacopeia*, 19th revision, U.S. Pharmacopelal Convention, Inc. pages 666 to 667, (1975).

Example 15

1. Synthesis of poly[oxy succinoyloxy dodecane-1,12-di(amidocarbonylmethylene)-co-10%-3-oxapentane-1,5-di(carbonyloxy)dodecane-1,12-di(amidocarbonylmethylene)].

A five-gallon glass-lined reaction kettle equipped with a reflux condenser, pyrometer, addition funnel, and dry nitrogen purge was charged with exactly 1,165 g (3.67 moles) of 1,12-di(hydroxyacetamido)dodecane prepared according to the procedure in Example 1, and 3 gallons of chlorobenzene. The reaction kettle was heated by means of a steam jacket to 130°C for 30 minutes with

stirring to insure complete dissolution of the monomer. The stirring speed was then increased to the maximum setting and a mixture of exactly 63.3 g (0.37 moles) of vacuum redistilled diglycyl chloride and 511.5 g (3.30 moles) of vacuum redistilled succinyl chloride added through the addition funnel during the time course of 6 minutes and 45 seconds. The reaction mixture was stirred and refluxed for an additional 2 hours after which time the stirring rate was decreased and the mixture allowed to cool at room temperature. The granular product was collected on a large ceramic filter, rinsed with tetrahydrofuran, and placed in a vacuum oven at 130°C. After heating the product at 130°C under partial vacuum and a slow stream of dry nitrogen for 5 days, the inherent viscosity was 0.58 (0.5% in TFE at 30°C).

2. Fiber evaluation

The above polymer was melt-extruded and oriented as in Example 1 to produce 2—0 suture size fiber with a tenacity of 4.11 g/denier, 26.8% elongation, and modulus of 20.5 g/denier. The knot strength was 58% of the tensile strength.

3. *In vivo* evaluation

The above fiber was implanted in mice as described in Example 1. The strength loss results are shown in Table 3 and in the accompanying figure.

TABLE 3

	Days Post Implantation	Tensile Strength Retained
25	7	89.7%
	14	83.9%
30	28	79.4%
	49	38.2%

At eight months post-implantation the encapsulated fiber was broken into small fragments, 1 to 4 mm in length. These fragments were extremely soft and partially absorbed. The implantation site in each of the mice showed no visible inflammation or other evidence of an adverse reaction toward the polymer.

Example 16

1. Synthesis of poly[oxysuccinoyloxydodecane-1,12-di(amidocarbonylmethylene)-co-20%-oxy-succinoyloxy-4,9-dioxadodecane-1,12-di(amidocarbonylmethylene)].

This polymer was prepared under exactly the same conditions described in Example 14 using 1,264 g (4.00 moles) of 1,12-di(hydroxyacetamido)dodecane prepared according to the procedure in Example 1, 320 g (1.00 mole) of 1,12-di(hydroxyacetamido)-4,9-dioxadodecane prepared according to the procedure in Example 10, 775 g (5.00 moles) of vacuum redistilled succinyl chloride, and 3.5 gallons of chlorobenzene. The succinyl chloride was added during the time course of 5 minutes and 10 seconds and the product was dried for 2 days at 130°C to give an inherent viscosity of 0.99 (0.5% in TFE at 30°C).

2. Fiber evaluation.

The above polymer was melt-extruded and oriented as in Example 1 to produce 2—0 suture size fiber with a tenacity of 4.67 g/denier, 38.2% elongation, and modulus of 18.0 g/denier. The knot strength was 64% of the tensile strength.

3. *In vivo* evaluation.

The above fiber was implanted in mice as described in Example 1. The strength loss results are shown in Table 4.

TABLE 4

	Days Post Implantation	Tensile Strength Retained
5	7	89.2%
	14	87.4%
10	28	76.6%
	49	57.3%

At eight months post-implantation the encapsulated fiber was broken into small fragments, 1 to 2 mm in length. These fragments were extremely soft and partially absorbed. The implantation site in each of the mice showed no visible inflammation or other evidence of an adverse reaction toward the polymer.

Example 17

1. synthesis of poly[oxy succinoyloxy dodecane-1,12-di(amidocarbonylmethylene)].

This polymer was prepared under the same conditions described in Example 14 using 1,081.4 g (3.42 moles) of 1,12-di(hydroxyacetamido)dodecane prepared according to the procedure in Example 1, 530.4 g (3.42 moles) of vacuum redistilled succinyl chloride, and 3 gallons of chlorobenzene. The succinyl chloride was added during the time course of 15 minutes and 13 seconds and the product was dried for 7 days at 130°C to give an inherent viscosity of 0.58 (0.5% in TFE at 30°C).

2. Fiber evaluation.

The above polymer was melt-extruded and oriented as in Example 1 to produce 2—0 suture size fiber with a tenacity of 5.03 g/denier, 31.0% elongation, and modulus of 22.0 g/denier. The knot strength was 50% of the tensile strength.

Claims

1. A body-absorbable polymeric surgical material characterised by a plurality of units of the general formula:

in which

- R¹ is hydrogen or methyl;
- R³ and R⁵ may be identical or different and are selected from the group consisting of the following, which may be linear or branched alkylene, alkylene having 1 to 2 nonadjacent catenary oxygen or sulfur atoms, and alkenylene; cycloalkylene and arylene; said members of the group having 4 to 25 carbon atoms in the cyclic compounds and from 2 to 25 carbon atoms in the non-cyclic compounds;
- R² and R⁴ are hydrogen or alkyl having 1 to 4 carbon atoms or R² and R⁴ together are linear or branched alkylene having one to four carbons forming with N—R³—N a heterocyclic group having 5 or 6 ring atoms; and
- a and b are independently zero or one.
2. The body-absorbable polymeric surgical material of claim 1 further characterised by the feature that a and b are zero and R⁵ is ethylene.
3. The body-absorbable polymeric surgical material of claim 2 further characterised by the feature that R¹, R², and R⁴ are hydrogen and R³ is a mixture of 1,12-dodecamethylene and 1,12-(4,9-dioxadodecamethylene).
4. The body-absorbable polymeric surgical material of any one of claims 1 to 3 further characterised by the feature that said material has 10 to 100 segments of repeating units of said polymer.
5. The body-absorbable surgical material of claim 4 further characterised by the feature that said material has 30 to 50 segments of repeating units of said polymer.
6. The body-absorbable surgical material of any one of claims 1 to 5 further characterised by the feature that said material is in the form of at least one filament.
7. The body-absorbable surgical material of claim 6 further characterised by the feature that said filament is in the form of a suture.

8. A process for making a body-absorbable polymeric surgical material of claim 1 which comprises the steps of:

reacting a diamine with lactic or glycolic acid to form a diamidediol;

and reacting said diamidediol with a bischloroformate or a diacid compound which is selected from dicarboxylic acids, methyl and ethyl esters of dicarboxylic acids, diacidchlorides, and anhydrides of dicarboxylic acids.

9. The process of claim 8 further characterised by the feature that said diacid compound is succinyl chloride.

10. The process of either of claims 8 and 9 further characterised by the feature that said diamidediol is a mixture comprised of 1,12-di(hydroxyacetamido)-4,9-dioxadodecane and 1,12-di(hydroxyacetamide)dodecane.

11. The method of any one of claims 8 to 10 further characterised by the feature that said diamine is one or both of 1,12-dodecanediamine and 4,9-dioxadodecane-1,12-diamine.

12. The process of any one of claims 8 to 11 further characterised by the feature that said diamidediol is placed in a solvent prior to reacting with said diacid compound or said bischloroformate.

13. The process of claim 12 further characterised by the feature that said solvent is selected from the group consisting of chlorobenzene, 1,1,2-trichloroethane and 1,4-dioxane.

14. The process of either of claims 12 and 13 further characterised by an additional step of removing said solvent after reacting with said compound or said bischloroformate.

Revendications

1. Matière chirurgicale polymère absorbable par l'organisme, caractérisée par plusieurs motifs de formule générale:

où

R¹ est un hydrogène ou un méthyle;

R³ et R⁵ peuvent être identiques ou différents et sont choisis parmi le groupe composé par les constituants suivants qui peuvent être un alkylène linéaire ou ramifié, un alkylène ayant 1 à 2 atomes d'oxygène ou de soufre caténaux non adjacents et un alcénylène; un cycloalkylène et un arylène; lesdits constituants du groupe ayant 4 à 25 atomes de carbone dans les composés cycliques et 2 à 25 atomes de carbone dans les composés non cycliques;

R² et R⁴ sont un hydrogène ou un alkyle ayant 1 à 4 atomes de carbone ou R² et R⁴, ensemble, sont un alkylène droit ou ramifié ayant 1 à 4 carbones formant avec N—R³—N un groupe hétéro-cyclique ayant 5 ou 6 atomes cycliques; et

a et b sont indépendamment zéro ou un.

2. Matière chirurgicale polymère, absorbable par l'organisme, de la revendication 1, caractérisée de plus en ce que a et b sont zéro et R⁵ est un éthylène.

3. Matière chirurgicale polymère, absorbable par l'organisme, de la revendication 2, caractérisée de plus en ce que R¹, R² et R⁴ sont un hydrogène et R³ est un mélange de 1,12-dodécaméthylène et de 1,12-(4,9-dioxadodécaméthylène).

4. Matière chirurgicale polymère, absorbable par l'organisme, de l'une des revendications 1 à 3, caractérisée de plus en ce que ladite matière a 10 à 100 segments de motifs dudit polymère.

5. Matière chirurgicale, absorbable par l'organisme, de la revendication 4, caractérisée de plus en ce que ladite matière a 30 à 50 segments de motifs dudit polymère.

6. Matière chirurgicale, absorbable par l'organisme, de l'une quelconque des revendications 1 à 5, caractérisée de plus en ce que ladite matière est sous forme d'au moins un filament.

7. Matière chirurgicale, absorbable par l'organisme, de la revendication 6, caractérisée de plus en ce que ledit filament est sous forme d'une suture.

8. Procédé pour préparer une matière chirurgicale polymère, absorbable par l'organisme, de la revendication 1, qui comprend les stades de:

— réaction d'une diamine avec l'acide lactique ou glycolique pour former un diamidediol;

— et réaction dudit diamidediol avec un bischloroformate ou un composé de type diacide qui est choisi parmi les acides dicarboxyliques, les esters méthyliques et éthyliques des acides dicarboxyliques, les chlorures de diacides et les anhydrides d'acides dicarboxyliques.

9. Le procédé de la revendication 8, caractérisé de plus en ce que ledit composé de type diacide est le chlorure de succinyle.

10. Le procédé de l'une des revendications 8 et 9, caractérisé de plus en ce que ledit diamidediol

est un mélange constitué de 1,12-di(hydroxyacétamido)-4,9-dioxadodécane et de 1,12-di(hydroxyacétamido)dodécane.

11. Le procédé de l'une quelconque des revendications 8 à 10, caractérisé de plus par le fait que ladite diamine est la 1,12-dodécanediamine et/ou la 4,9-dioxadodécane-1,12-diamine.

12. Le procédé de l'une quelconque des revendications 8 à 11, caractérisé de plus en ce que ledit diamiddiol est placé dans un solvant avant la réaction avec ledit composé de type diacide ou le bischloroformiate.

13. Le procédé de la revendication 12, caractérisé de plus en ce que ledit solvant est choisi parmi le groupe constitué par le chlorobenzène, le 1,1,2-trichloroéthane et le 1,4-dioxanne.

14. Le procédé de l'une des revendications 12 et 13, caractérisé de plus par un stade additionnel d'élimination dudit solvant après la réaction avec ledit composé ou ledit bischloroformiate.

Patentansprüche

1. Vom Körper absorbierbares, polymeres chirurgisches Material, gekennzeichnet durch mehrere Einheiten der allgemeinen Formel

in der R¹ Wasserstoff oder Methyl ist, R³ und R⁵ identisch oder verschieden sein können und ausgewählt sind aus der folgenden Klasse der folgenden Gruppen: lineares oder verzweigtes Alkyl, Alkyl mit einem oder zwei nichtbenachbarten Kettensauerstoff- oder Kettenschwefelatomen, und Alkenyl; Cycloalkyl und Aryl, wobei die genannten Angehörigen der Klasse bei den zyklischen Verbindungen 4 bis 25 Kohlenstoffatomen und bei den nichtzyklischen Verbindungen 2 bis 25 Kohlenstoffatomen haben können, R² und R⁴ Wasserstoff oder ein Alkyl mit 1 bis 4 Kohlenstoffatomen oder R² und R⁴ zusammen ein lineares oder verzweigtes Alkyl mit ein bis vier Kohlenstoffatomen sein können, das mit N—R³—N eine heterocyclische Gruppe mit 5 oder 6 Ringatomen bildet, und a und b unabhängig voneinander Null oder eins sind.

2. Vom Körper absorbierbares, polymeres chirurgisches Material nach Anspruch 1, dadurch gekennzeichnet, daß a und b Null sind und R⁵ Äthyl ist.

3. Vom Körper absorbierbares, polymeres chirurgisches Material nach Anspruch 2, dadurch gekennzeichnet, daß R¹, R² und R⁴ Wasserstoff sind und R³ ein Gemisch von 1,12-Dodecamethylen und 1,12-(4,9-Dioxadodecamethylen) ist.

4. Vom Körper absorbierbares, polymeres chirurgisches Material nach einem der Ansprüche 1 bis 3, dadurch gekennzeichnet, daß das genannte Material 10 bis 100 Segmente aus sich wiederholenden Einheiten des genannten Polymerisats besitzt.

5. Vom Körper absorbierbares chirurgisches Material nach Anspruch 4, dadurch gekennzeichnet, daß das genannte Material 30 bis 50 Segmente aus sich wiederholenden Einheiten des genannten Polymerisats besitzt.

6. Vom Körper absorbierbares Material nach einem der Ansprüche 1 bis 5, dadurch gekennzeichnet, daß das genannte Material in Form mindestens eines Filaments vorliegt.

7. Vom Körper absorbierbares chirurgisches Material nach Anspruch 6, dadurch gekennzeichnet, daß das genannte Faden in Form von chirurgischem Nahtmaterial vorliegt.

8. Verfahren zur Herstellung eines vom Körper absorbierbaren, polymeren chirurgischen Materials nach Anspruch 1, mit folgenden Schritten:

Umsetzen eines Diamins mit Milch- oder Glykolsäure zur Bildung eines Diamiddiols; und

Umsetzen des Diamiddiols mit einem Bischlorformiat oder einer Disäureverbindung, die ausgewählt ist aus der Klasse der Dicarbonsäuren, Methyl- und Äthylester von Dicarbonsäuren, Disäurechloride und Dicarbonsäureanhydride.

9. Verfahren nach Anspruch 8, dadurch gekennzeichnet, daß das genannte Disäureverbindung Bernsteinsäurechlorid ist.

10. Verfahren nach Anspruch 8 oder 9, dadurch gekennzeichnet, daß das genannte Diamiddiol ein Gemisch aus 1,12-Di(hydroxyacétamido)-4,9-dioxadodécane und 1,12-Di(hydroxyacétamido)dodécane ist.

11. Verfahren nach einem der Ansprüche 8 bis 10, dadurch gekennzeichnet, daß das genannte Diamin aus 1,12-Dodecandiamin und 4,9-Dioxadodécane-1,12-diamin ist.

12. Verfahren nach einem der Ansprüche 8 bis 11, dadurch gekennzeichnet, daß das genannte Diamiddiol vor seiner Umsetzung mit der genannten Disäureverbindung oder dem bischlorformiat in ein Lösungsmittel eingebracht wird.

0 030 822

13. Verfahren nach Anspruch 12, dadurch gekennzeichnet, daß das genannte Lösungsmittel ausgewählt aus der Klasse Chlorbenol, 1,1,2-Trichloräthan und 1,4-Dioxan ist.

14. Verfahren nach Anspruch 12 oder 13, dadurch gekennzeichnet, daß nach dem Umsetzen der genannten Verbindung oder des genannten Bischlorformlats das genannte Lösungsmittel in einem
5 zusätzlichen Schritt entfernt wird.
